Establishment of an explicit relationship between stress and strain (load and deformation) has been the holy grail of modelling mechanical behaviour of materials. Geomaterials have very complex and interesting mechanical behaviour including pressure dependence, time dependence, fracture, and severe plastic deformation accompanied by volume change, very small range of elastic behaviour. In the past, an extreme reliance of empiricism was the norm, and modelling mechanical behaviour of geomaterials with a strong theoretical underpinning has been possible, especially after the 1960s. Folding in the basic tenet of the mathematical theory of plasticity into a framework of critical state soil mechanics revolutionized constitutive modelling of geomaterials. The implementation of such complex continuum models into design has also made engineering of foundations and earth structures optimal and a lot more reliable.

The ambit of what can be considered a geomaterial (such as landfills, composites including geotextiles–soils, reinforced earth) is ever increasing. In the recent times, the introduction of hypoplastic and hyperplastic frameworks has enabled tackling materials of complex constitutivity for applications beyond just infrastructure to areas such as energy storage, waste management, mining, and powder technology. Additionally, migration towards the discrete

element, material point, and particle hydrodynamics approaches for a multiple-length-scale understanding of the mechanical behaviour have not only increased the challenges in modelling, but also provided a deeper understanding of material behaviour. Important advances continue to be made in the geomechanics, soft condensed matter physics, rheology, and geoen지니어ing communities on modelling of geomaterials. With the objective of highlighting recent trends in constitutive modelling and implementation, the Indian Geotechnical Journal is bringing forth this special issue on “Constitutive Modelling of Geomaterials”.

This issue comprises seven articles that encompass constitutive modelling of geomaterials highlighting various aspects such as stress and material anisotropy, multi-physical effects, micromechanics, and numerical implementation.

It is well known that stress-induced anisotropy affects the fabric of clay. Chen et al. propose a rotational hardening model that reorients the yield surface as a function of loading history accounting for the effects of stress-induced anisotropy in clay. Fuentes and Lascarro address the importance of experimental methodology and consequent fabric evolution on the response of geomaterials. Such an effect is cast within a hypoplastic framework that captures the material anisotropy induced during cylindrical sample preparation for triaxial experiments. Multi-physical effects such as chemical, thermal, and hydraulic play a crucial role in the deformation response of various geoen지니어ing problems (nuclear waste management, geothermal energy, and chemical weathering).

Shirash et al. incorporate such effects within the critical state framework. In this study, thermal creep on sand–bentonite mixture is modelled.
