## Abstract

Rheumatoid arthritis is a chronic, systemic inflammatory disease, with certain evidence of multiple factors involved, but also with the strong autoimmune component, leading to a high potential for disability, through synovial inflammation and joint destruction. Diagnostic methods and management possibilities have recently improved, thus leading to a better outcome, based on the treat to target recommendation. Although biologic agents represent efficient therapeutic agents, in the last few years, the advances in understanding the mediators involved in rheumatoid arthritis pathogenesis have provided new targeted therapies, represented by small molecule inhibitors against the Janus kinases that contribute in the signaling pathways of various cytokine receptors.

## 1. Introduction

Rheumatoid arthritis (RA) is a chronic, autoimmune, systemic disease that targets primarily the synovial joint lining and causes progressive disability. Untreated, PR leads to the destruction of the joints by the erosion of cartilage and bone material. Loss of physical function is the aftermath, which is why early treatment is vital for controlling disease activity and for preventing joint damage.

Angiogenesis is an important process for the growth and development of all tissues, during which new blood vessels are formed from pre-existing vascularization and play a critical role in the pathogenesis of several inflammatory autoimmune diseases, such as PR. Angiogenesis is triggered by the dominance of pro-angiogenic factors over endogenous angiostatic mediators. Studies conducted over the past two decades have suggested the involvement of numerous pro-angiogenic factors such as metabolites, ions, growth factors, hypoxia-inducible
