Accelerated Testing, 2006 Introduction Probability fundamentals Distributions Parameter estimation Accelerated test plans Accelerated testing models Environmental stress screening Test equipment methods and applications [How to Plan an Accelerated Life Test](#) William Q. Meeker, Gerald J. Hahn, 1985 **Advanced Data Analysis and Test Planning for Highly Reliable Products** Ye Zhang, 2014 Accelerated life testing ALT has been widely used in collecting failure time data of highly reliable products Most parametric ALT models assume that the ALT data follows a specific probability distribution However the assumed distribution may not be adequate in describing the underlying failure time distribution In this dissertation a more generic method based on a phase type distribution is presented to model ALT data To estimate the parameters of such Erlang Coxian based ALT models both a mathematical programming approach and a maximum likelihood method are developed To the best of our knowledge this dissertation demonstrates for the first time the potential of using PH distributions for ALT data analysis To shorten the test time of ALT degradation tests have been studied as a useful alternative

Among many degradation tests destructive degradation tests DDT have attracted much attention in reliability engineering. Moreover, some materials/products start degrading only after a random degradation initiation time that is often not even observable. In this dissertation, two-stage delayed degradation models are developed to evaluate the reliability of a product with random initiation time. For homogeneous and heterogeneous populations, fixed effects and random effects Gamma processes are considered, respectively. An expectation maximization algorithm and a bootstrap method are developed to facilitate the maximum likelihood estimation of model parameters and to construct the confidence intervals of the interested reliability index, respectively. With an Accelerated DDT model, an optimal test plan is presented to improve the statistical efficiency. In designing the ADDT experiment, decision variables related to the experiment must be determined under the constraints on limited resources such as the number of test units and the total testing time. In this dissertation, the number of test units and stress level are pre-determined in planning an ADDT experiment. The goal is to improve the statistical efficiency by selecting/appropriately allocating the test units to different stress levels to minimize the asymptotic variance of the estimator of the p quantile of failure time. In particular, considering the random degradation initiation time, a three-level constant stress destructive degradation test is studied. A mathematical programming problem is formulated to minimize the asymptotic variance of reliability estimate.

Data Analysis and Experimental Design for Accelerated Life Testing with Heterogeneous Group Effects Kangwon Seo, 2017. In accelerated life tests, ALTs, complete randomization is hardly achievable because of economic and engineering constraints. Typical experimental protocols such as subsampling or random blocks in ALTs result in a grouped structure which leads to correlated lifetime observations. In this dissertation, generalized linear mixed model (GLMM) approach is proposed to analyze ALT data and find the optimal ALT design with the consideration of heterogeneous group effects. Two types of ALTs are demonstrated for data analysis. First, constant stress ALT (CSALT) data with Weibull failure time distribution is modeled by GLMM. The marginal likelihood of observations is approximated by the quadrature rule and the maximum likelihood (ML) estimation method is applied in iterative fashion to estimate unknown parameters including the variance component of random effect. Secondly, step stress ALT (SSALT) data with random group effects is analyzed in similar manner but with an assumption of exponentially distributed failure time in each stress step. Two parameter estimation methods from the frequentist's and Bayesian points of view are applied and they are compared with other traditional models through simulation study and real example of the heterogeneous SSALT data. The proposed random effect model shows superiority in terms of reducing bias and variance in the estimation of life stress relationship. The GLMM approach is particularly useful for the optimal experimental design of ALT while taking the random group effects into account. In specific planning, ALTs under nested design structure with random test chamber effects are studied. A greedy two-phased approach shows that different test chamber assignments to stress conditions substantially impact on the estimation of unknown parameters. Then, the D-optimal test plan with two test chambers is constructed by applying the quasi-likelihood

approach Lastly the optimal ALT planning is expanded for the case of multiple sources of random effects so that the crossed design structure is also considered along with the nested structure *Development of Statistical Models for Data Analysis*
