

Subsurface drainage and surface water management for salinity control

Neil Coles and Sylvia Tellow, Engineering Water Management Group, Department of Agriculture

The problem

Salinity, waterlogging and soil structure decline are major threats to maintaining agricultural productivity, water resources and biodiversity in the south-west agricultural region of Western Australia. Under the current land management practices soil and land degradation caused by these issues will affect the productivity of up to 30 per cent of the agricultural area by 2050. If we are to reduce the area impacted then management action needs to be taken now.

This Farmnote provides information on engineering options for salinity control. Information on vegetation options to control salinity, such as the use of perennial pastures and revegetation, is available from the Department of Agriculture.

Water management systems

Excess water in the landscape can be managed using engineering options such as shallow or deep drains and, in some situations, groundwater pumping or relief wells. These structures are designed to control run-off, to lower groundwater tables and reduce the effects of water erosion, waterlogging, flooding, groundwater recharge, groundwater discharge, high watertables and salinity. Effective water management can reduce productivity losses caused by excess water.

A system to manage excess water can include:

- **surface water management** options, through the construction of broad based channels, grade banks or shallow drains;
- **subsurface drainage or groundwater management** options, through deep drains, relief wells, siphons or pumping.

Management of excess water also includes methods for disposal of discharge, such as the development of on-farm water resources (dams, bores, water distribution systems) for fresh water, or detention storage and evaporation basins for low quality or saline water.

Water management systems are complex and need to be carefully planned and evaluated prior to construction to gauge their impact. Surface water management and subsurface drainage target quite different problems with different engineering techniques. Their impact both on- and off-site needs careful consideration, particularly in regard to neighbouring properties.

Subsurface drainage

Problems arising from groundwater recharge and high watertables can be tackled through deep drainage or pumping. Issues to consider when developing a drainage management plan include:

- the assessment of on-site characteristics (soils, geology, and gradient of slopes) to establish the potential for effective drainage. Deep drains constructed in heavy, clay soils in the lower landscape are generally not effective in lowering the watertables, while drains in coarse, sandy soils are often unstable and prone to erosion;
- determining the permeability or rate at which water will flow from the soil into a deep drain, or the rate at which it can be extracted using a pump. This will establish the area affected by the drain or pump and can be useful in estimating the amount of water likely to be discharged. For example, sandy, coarse soils have high permeability, whereas heavy, clay soils have low permeability;
- assessing the best areas for subsurface drainage. The greatest economic benefit can be achieved where high value crops are to be protected, such as the drainage system on the Swan Coastal Plain to establish the horticulture and dairy industries;

Using a combination of systems, such as drains, banks, roaded catchments and dams, is likely to produce the best results when trying to manage surface water and near surface recharge.
