Abstract

Background: Traumatic brain injury (TBI) is a leading cause of cognitive impairment, affecting memory, attention, and executive function. Cognitive rehabilitation strategies have been developed to mitigate these deficits, but their effectiveness varies across populations and intervention types. This scoping review explores the existing literature on cognitive rehabilitation interventions for individuals with TBI, identifying key strategies, their efficacy, and research gaps.

Methods: A systematic search of peer-reviewed studies published between 2000 and 2024 was conducted across multiple databases, viz PubMed, Scopus, and Web of Science. Studies examining cognitive rehabilitation strategies for TBI patients, including computer-based cognitive training (CBCT), compensatory strategy training, metacognitive training, and mindfulness-based interventions, were included. Articles were screened for relevance, and data were synthesised to compare the efficacy of different rehabilitation strategies.

Results: Seventy-five studies met the inclusion criteria. The most commonly used interventions were CBCT (n=27), compensatory strategy training (n=24), metacognitive training (n=15), and mindfulness-based interventions (n=9). Improvements were observed in memory (70% of studies), attention (60%), and executive function (50%), with compensatory strategy training and metacognitive approaches demonstrating notable benefits. However, variations in study design, intervention protocols, and follow-up duration limited direct comparisons. Functional outcomes, such as daily living skills and quality of life, improved in 40% and 30% of studies, respectively.

Conclusion: Cognitive rehabilitation strategies offer significant potential for improving cognitive and functional outcomes in TBI patients. However, inconsistencies in methodologies and intervention effectiveness highlight the need for standardised protocols and personalised approaches. Future research should focus on optimising intervention designs, integrating emerging technologies, and conducting long-term follow-up studies to enhance rehabilitation efficacy and accessibility.

Keywords: Traumatic Brain Injury, Cognitive Rehabilitation, Memory, Executive Function, Attention, Neurorehabilitation, Metacognition, Compensatory Strategies

Key Message: Cognitive rehabilitation is not a one-size-fits-all solution for traumatic brain injury (TBI). While interventions show promise, inconsistencies in methodologies limit their impact. Future research must refine strategies, personalise treatments, and harness technology to bridge the gap between science and real-world recovery, ensuring meaningful cognitive and functional improvements for TBI patients.

INTRODUCTION

Traumatic brain injury (TBI) is a significant global health concern, affecting over 69 million individuals annually and contributing to long-term disability and reduced quality of life.¹ TBI results from external forces such as falls, road traffic accidents, or sports-related injuries, leading to structural and functional damage to the brain.

²The cognitive sequelae of TBI—including memory deficits, impaired attention, executive dysfunction, and slowed information processing—are among the most debilitating consequences, often persisting long after the acute phase of injury. ³These cognitive impairments not only hinder daily functioning but also impose substantial emotional and financial burdens on individuals, families, and healthcare systems.^{4,5}

Cognitive rehabilitation has emerged as a cornerstone of TBI management, aiming to restore lost cognitive functions, compensate for deficits, and enhance the overall quality of life.⁶ The field encompasses a wide range of interventions, from traditional compensatory strategies and restorative training to innovative technology-assisted approaches. ⁷Compensatory techniques, such as the use of external aids (e.g., diaries, smartphones) and environmental modifications, focus on adapting the individual's surroundings to mitigate cognitive challenges.⁸ In contrast, restorative approaches, including computerised cognitive training (CCT) and neuropsychological exercises, aim to rebuild cognitive capacities through repetitive practice and neuroplasticity. ⁹Despite the diversity of available interventions, the efficacy of cognitive rehabilitation remains
