Evidence-based Laboratory Medicine Christopher P. Price, Robert H. Christenson, 2007 *Biomarkers for Early Diagnosis of Alzheimer's Disease* Daniela Galimberti, Elio Scarpani, 2008 Alzheimer s disease AD is characterized by the deposition into the brain of amyloid peptide

which originates a cascade of inflammatory events leading eventually to neuronal death. These pathological events likely occur several years before the clinical manifestation of the disease, implying that potential therapeutical interventions are currently started too late to give beneficial results. Recently, growing attention has been paid to the Mild Cognitive Impairment (MCI) considered the prodromal phase of AD as 80% of subjects with MCI have been shown to develop AD within 5 years. Several studies aimed to identify biological markers to differentiate between normal aging and incipient AD have been carried out including cerebrospinal fluid (CSF) analysis and neuroimaging. In particular, the evaluation of CSF Amyloid beta 1-42 levels together with tau and phospho-tau are of help for recognizing early AD. Besides a number of additional molecules are altered in CSF. Other early modifications have been observed in peripheral cells such as fibroblasts and leukocytes as well as in serum from patients. Biomarkers for AD represent important tools supporting the clinical diagnosis and the choice of potential therapeutic options. Moreover, they would be of great help for the selection of cohorts of homogeneous patients for clinical trials with new disease-modifying compounds. This book is aimed to give an update about MCI as prodromal Alzheimer's disease (AD) to discuss the main known pathological mechanisms at the basis of AD and to describe the possible biomarkers to be used for an early diagnosis of the disease.

Cancer Biomarkers Committee on Developing Biomarker-Based Tools for Cancer Screening, Diagnosis, and Treatment, Institute of Medicine, 2007-03-30. Many cancer patients are diagnosed at a stage in which the cancer is too far advanced to be cured and most cancer treatments are effective in only a minority of patients undergoing therapy. Thus, there is tremendous opportunity to improve the outcome for people with cancer by enhancing detection and treatment approaches. Biomarkers will be instrumental in making that transition. Advances in biotechnology and genomics have given scientists new hope that biomarkers can be used to improve cancer screening and detection, to improve the drug development process, and to enhance the effectiveness and safety of cancer care by allowing physicians to tailor treatment for individual patients, an approach known as personalized medicine. However, progress overall has been slow despite considerable effort and investment, and there are still many challenges and

obstacles to overcome before this paradigm shift in oncology can become a reality
