

Advanced SEM Imaging with the Trinity Detection System

Petr Wandrol, EJF Vesseur,
Radovan Vasina, Alex Ilitchev

Introduction

Fundamentally, the quality of a scanning electron microscope (SEM) image depends on the quality of the detected electrons. Although traditional SEM design employs an Everhard-Thornley detector (ETD) for secondary electrons (SE) and a below-the-lens detector for backscattered electrons (BSE), advanced SEMs can potentially be equipped with multiple in-lens detectors. As these can collect both SE and BSE signals, the observed electrons could be sorted according to their energies and/or emission angles. The Thermo Scientific™ Trinity™ Detection System, available in the Thermo Scientific™ Apreo SEM (with NiCol column) and Scios™ DualBeam, is described here. It consists of three detectors: two in-lens (T1, T2) and one in-column (T3). This unique system offers unparallelled SE and BSE contrast as well as detailed information on sample composition, morphology, surface features, and more.

Figure 1. Schematic drawing of the NiCol column with the Trinity Detection System. T1 and T2 are in-lens, whereas T3 is in-column.

Trinity Detection System

The Trinity detectors are placed along an A-tube biased at 8 kV; the potential of the A-tube attracts signal electrons to them (Figure 1). Positioned very low in the column is T1, which detects the intense signal of the high-energy backscattered electrons. Secondary electrons do not have the energy to reach the T1 detector; the electric field instead focuses them into the hole of T1, and they are subsequently detected by the T2 detector. Secondary electrons with even lower energy (<2 eV) pass T2 and are detected by the T3 detector (Figure 2).

Figure 2. Illustration of the SE and BSE trajectories in the Trinity Detection System at analytical working distance (AWD). SE, influenced by the electric field, bend toward the beam axis and pass to T2 and T3. BSE are less sensitive and are detected by T1.
