

Cardiac computed tomography (CT)

A cardiac CT scan is an ECG-triggered scan of the heart using X-rays. Cardiac CT scans can be used to evaluate the morphology of the heart and pericardium, the heart valves and the dimensions of the atria and ventricles. A cardiac CT without iodine contrast is used to assess the amount of coronary calcification (calcium score). A CT coronary angiogram (CCTA), with iodine contrast, is used to evaluate the coronary arteries, assess the presence of plaque and quantify the degree of stenosis. For all diagnostic questions related to the heart and coronaries, apart from calculating a calcium score, iodine contrast is required. See Figure 1 and 2. Indications for cardiac CT include: calculation of the calcium score to evaluate cardiovascular risk around treatment thresholds in asymptomatic individuals, evaluation of coronary stenosis in symptomatic patients at lower pre-test probability (in particular to exclude coronary artery disease). Relative contraindications to cardiac CT are pregnancy and contrast allergy. The quality of CT scans can be degraded by atrial fibrillation, fast heart rates, and intracardiac devices due to scattering artefacts.

Figure 1 A Normal cardiac CT
A: Calcium score 0 B: No soft plaque on CCTA

Figure 2 A: Agatston score of ICD on cardiac CT without contrast, B: on CCTA with RCA reconstruction only shows focal calcification (white arrows), no soft plaque, stenosis degree 25-50%.

The calcium score, also known as the Agatston score, is used to assess the extent of coronary artery calcification. This score, assigned based on the calcium density in Hounsfield units (HU) reflects the risk of a major adverse cardiac event.

Coronary CT angiography has high accuracy to exclude and detect coronary plaque and stenosis in patients with chest pain and lower pretest probability.

Severe calcification results in 'blooming' which leads to overestimation of stenosis degree. Depending on the scanner technology, high or irregular heart rates could result in motion or step artefacts.

Cardiac MRI

A cardiac MRI is a scan of the heart made using electromagnetic waves. It can be used to obtain static and dynamic images of the heart, visualising ventricular function, valvular function, myocardial pathology and quantify blood flow. A cardiac MRI, without and with gadolinium contrast, is an excellent technique to characterise cardiac tissue, including oedema, post-infarct scarring, fibrosis, and fat (see Figure 3 and 4). Furthermore, stress MRI can be performed by administering regadenoson or adenosine. Indications for a cardiac MRI scan include cardiomyopathy, congenital heart disease, evaluation of the myocardium (e.g. ischaemia, post-infarction, ID). Cardiac MRI enables tissue characterisation by identifying the proportion of fat, water and fibrosis in the tissue, with a gadolinium based contrast agent. Contraindications to a cardiac MRI scan may include temporary pacemaker leads, insulin pumps and metallic foreign bodies in vivo. Relative contraindications to an MRI scan depending on the type of intracardiac device are pacemakers and ICDs, and claustrophobia.

For the detection of myocardial ischaemia the contrast enhancement sequences during stress are essential. Imaging in rest is not required for the diagnosis.

- Ischaemia: subendocardial perfusion defect, no delayed contrast enhancement;
- Infarction: subendocardial perfusion defect and delayed contrast enhancement (indicating scarring/fibrosis) of the same region.
