

Electrocardiogram

Introduction

Electrocardiography is the recording, usually from electrodes on the body surface, of the electrical activity of the heart during the cardiac cycle. Before each part of the heart contracts there is a change in the membrane potential of the cardiac muscle cells, this *depolarization* precedes contraction. Then there is a *repolarization* of the cardiac muscle, which precedes relaxation.

An ECG is usually recorded using 12 leads, i.e. 12 samples recorded with standard connections between patient and machine.

For this course there are broadly two types of information that you should be able to acquire from an ECG:

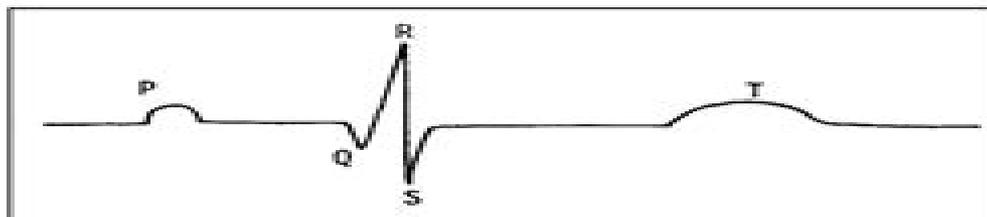

- **Timing information:** i.e. rate, rhythm, conduction times, pacing and whether there are ectopic foci; these can be assessed from a any single lead of an ECG. A long sample of one lead is often called a "rhythm strip".
- **Directional information:** i.e. vectors of depolarization and repolarization; these require more than one lead to assess.

ECG recording – Theory

The shape of the recorded electrocardiogram depends on:

- the sequence of depolarization and repolarization of the cardiac muscular mass
- the position of the recording electrodes relative to the heart.

The shape of the normal ECG
