Quantal Response Analysis in the Absence of a Zone of Mixed Results Using Data Augmentation, 2008 Quantal response analysis is used to estimate the probability of a dichotomous response e g complete penetration as a function of a stimulus variable Using maximum likelihood and the DiDonato Janagin algorithm estimates of the normal distribution parameters that underlie threshold stimulus levels are obtainable if a zone of mixed results is observed in the test data and if the average success producing stimulus exceeds the average failure producing stimulus In the absence of a zone of mixed results a method is proposed that utilizes data augmentation to estimate some parameter of interest e g the probability of success at a specific stimulus level This method generates artificial copies of the original data set of stimuli and responses and then adds a random noise component to each of the stimuli
