

Studying the mechanisms by which growth factors activate cellular functions has provided important insights into the normal pathways of cell growth and differentiation. Furthermore, such a study affords a basis for understanding how subversion of these pathways by defective proto-oncogenes leads to cancer. The interaction between growth factors and their appropriate receptors initiates a cascade of biochemical events during which protein phosphorylation and dephosphorylation play key roles in regulation of signal transduction and activation of effector functions. A UCLA Symposium on Cell Activation and Signal Initiation* highlighted recent progress in this area.

Transmembrane signaling via the antigen receptor on B and T lymphocytes involves polyphosphoinositide (PI) breakdown and formation of hydrolytic products that function as cellular second messengers. This mechanism is linked to a wide variety of agonist-receptor systems operating in numerous cell types and tissues. The current dogma of PI-dependent receptor signaling suggests that binding of a ligand to its specific membrane receptor results in phosphatidylinositol 4,5-bisphosphate (PIP₂) hydrolysis and formation of inositol 1,4,5-trisphosphate (IP₃) and 1,2-diacyl-glycerol (DG). The former increases intracellular Ca²⁺ concentrations, and the latter activates protein kinase C (PKC).

R. Irvine (Cambridge, UK) suggests that a third molecule, inositol 1,3,4,5-tetrakisphosphate (IP₄), promotes extracellular Ca²⁺ entry and has a synergistic effect with IP₃. Using lacrimal acinar cells, in which acetylcholine evokes sustained membrane hyperpolarization, Ca²⁺-activated K⁺ current can be evoked by intracellular perfusion of IP₄ in combination with IP₃. In this system, where hyperpolarization depends on extracellular Ca²⁺, neither IP₃ nor IP₄ is effective by itself. IP₄ also acts synergistically with IP₃ in activation of sea urchin eggs; however, the universal role of IP₄ in receptor-mediated signaling and, more specifically, in lymphoid cells has yet to be shown.

Protein kinase C expression and function

Previously, PKC was thought to be a simple entity, but in the past two years it has emerged as a family of structurally related proteins that differ in tissue distribution, cofactor dependency and substrate specificity. According to data presented by U. Kikkawa (Kobe University) and K.P. Huang (NIH, Bethesda), PKC γ (following the nomenclature of L. Coussens et al. (1986) *Science* 233, 859) is distributed only in brain tissue, specifically in cerebellar and Purkinje cells, whereas PKC α and PKC β are expressed in brain as well as in peripheral tissues. PKC β is the major subtype detected by immunoblot in human leukocytes, but PKC β and low levels of PKC α are detectable in spleen extracts. Tissue staining with anti-peptide antibodies that detect variable regions unique for PKC β I and PKC β II (the result of alternative splicing of the PKC β gene) reveals that the former is distributed in granular cells in the cerebellum, and the latter occupies cells that surround Purkinje cells. All PKC subtypes are inhibited by staurosporin; they bind phorbol 12,13-dibutyrate (PDBu) with similar affinity and are activated by similar concentrations of the phorbol ester. PDBu-mediated down-regulation of PKC is relatively fast for the β subtype (within five minutes) and slow for the α subtype (three hours). Furthermore, PKC γ is degraded by trypsin within one minute, but PKC α is relatively resistant to trypsin degradation. DG and phosphatidylserine enhance PKC α degradation by trypsin, suggesting that when these cofactors bind they induce conformational changes that expose the tryptic sites.

P. Parker (Ludwig Institute, Brussels) has identified a 76 kDa molecule in an extract of resting cells that is immunoreactive with anti-PKC antibodies. Stimulation of the cells with phorbol ester results in the appearance of a 79 kDa immunoreactive molecule, suggesting post-translational modification that might also result from PKC autophosphorylation. Whether one or both forms of PKC are in an active

state remains to be tested.

A recent contribution to the growing family of kinases is that of Y. Ono (Takeda Chemical Industries, Osaka), who reported the cloning and sequencing of three additional PKC-related genes (termed δ , ϵ and ζ). The new genes are homologous to α , β and γ PKC in the C1 regulatory domain, the C3 domain and the ATP-binding site and the C4 catalytic domain. However, they lack the conserved second domain, including the pseudosubstrate sequence. The new kinases phosphorylate histone proteins at serine and threonine residues but they are much less dependent for their activation on Ca²⁺ and phospholipids, suggesting that their physiological role may differ from that of the three known PKCs.

Mixed micelle techniques that have been used to investigate cofactor specificity and stoichiometry (R.M. Bell, Duke University) support a model wherein activated PKC forms a complex with one molecule of Ca²⁺, one molecule of DG and four molecules of phosphatidylserine.

The possible role of PKC in tumorigenicity has been tested by transfection of NIH 3T3 fibroblasts with the rat brain PKC γ gene (Bell and O.J. Finn, Duke University). As a result, transfectants have altered growth *in vitro* and enhanced tumorigenicity *in vivo*. Tumors that retain transfected sequences express fewer PKC γ transcripts than the parental lines, suggesting that high level expression of PKC γ may be a factor in cell transformation, but may not be obligatory for maintaining the malignant phenotype.

A model for lipid-mediated *in vivo* regulation of PKC activity has been formulated by Bell, who finds that sphingosine and lysosphingolipids inhibit PKC activity *in vitro* and PKC-mediated functions *in vivo* in several cell types. In accordance with this model, mutations leading to enhanced sphingolipid hydrolysis or decreased sphingolipid synthesis may affect cellular PKC activity and be indirectly involved in tumor progression.
